

## TVM Basic Concepts: B/C Ratio, IRR, and ERR

Module: 02.4

Revised: February 7, 2003

### Purpose:

- Expand TVM (time value of money) concepts into the development of other cashflow evaluation techniques besides NPV. Specifically:
  - B/C Ratio problems – Federally Funded
  - IRR & ROR – Internal Rate of Return - Banks
  - ERR – External Rates of Return

### Learning Objectives:

- Given appropriate data and making appropriate assumptions students should be able to determine the:
    - B/C Ratio
    - IRR, and
    - ERR
- For simple project cashflows.

### B/C Ratio is important because ... ..

- Most federally funded project require evaluation by B/C Ratio.
- 1937 Law stated that the benefits to whomever they may accrue must exceed the cost to the government.
- Various interpretations of exactly what that means.

### B/C Ratio

Conventional Equation

$$\text{B/C} = \text{Yearly Benefits} / \text{Yearly Costs to Gov.}$$

Modified Equation

$$\text{B/C} = \text{Yearly Net Benefits} / \text{Yearly Net Costs}$$

**Note:** every number is assumed to be annualized based on the same discount rate

### B/C Ratio Example with $i=0\%$

Every Benefit and Cost must be converted to an equivalent annual amount.

$$\text{UB} = 20 \quad \text{O\&M} = 5 \quad \text{IC} = 100 \quad \text{Yrs} = 10$$

$$\text{B/C} = \text{UB} / (\text{IC}/\text{Yrs} + \text{O\&M}) = 1.3$$

$$\text{B/C} = (\text{UB} - \text{O\&M}) / (\text{IC}/\text{Yrs}) = 1.5$$

## B/C Ratio with $i > 0$

|               |                             | AE          |
|---------------|-----------------------------|-------------|
| Initial Cost  | \$20,000,000                | \$3,116,402 |
| Salvage Value | 200,000                     | \$13,164    |
| Life = 10     | 10                          |             |
| Interest = 9% | 9%                          |             |
| User Benefits | 5,500,000                   |             |
| O&M           | \$2,000,000                 |             |
| Net Benefits  | = User Benefits - O&M       |             |
| Net Cost      | = AE of IC - AE of SV       |             |
| Modified B/C  | =                           | 1.13        |
| Benefits      | = User Benefits             |             |
| Costs         | = AE of IC - AE of SV + O&M |             |
| Conv B/C      | =                           | 1.08        |

The Costs are easy to quantify.

But what are user benefits?

Sometimes that's a judgment call.

## RAT #02.4.1

- Pull out a sheet of paper.
- Individually work in 5-minutes: Given a project life of 50 years, an Initial Cost of \$25-million, annual benefits are \$1.25-million and O&M costs are \$500k. Neglecting interest costs and salvage value, what is the B/C ratio using the modified formula?

## Typical Replacement Problem, B/C with $i < > 0\%$ , $n$ is finite

Three alternatives (A, B, and C) have been suggested to **replace** the current situation. Each of the alternatives has an expected life of 20 years with negligible salvage value. Use a 9% discount rate. Which would you pick using B/C ratio?

| $i=9\%$ , $n=20$ yrs | Current  | Project A | Project B | Project C |
|----------------------|----------|-----------|-----------|-----------|
| Initial Cost (\$)    | \$0      | \$100,000 | \$175,000 | \$225,000 |
| Annual O&M Cost      | \$15,000 | \$8,000   | \$10,000  | \$25,000  |
| Annual Benefits      | \$20,000 | \$30,000  | \$35,000  | \$50,000  |

The basic approach is to evaluate the differences between the current and each suggested alternative.

Step #1: Convert everything to annual using the  $A=P(A/P,9,20)$  relationship.

Step #2: Compute deltas

Step #3: Compute B/C and pick "best."

| $i=9\%$ , $n=20$ yrs   | Current  | Project A | Project B | Project C |
|------------------------|----------|-----------|-----------|-----------|
| Initial Cost (\$)      | \$0      | \$100,000 | \$175,000 | \$225,000 |
| Annual O&M Cost        | \$15,000 | \$8,000   | \$10,000  | \$25,000  |
| Annual Benefits        | \$20,000 | \$30,000  | \$35,000  | \$50,000  |
| Conventional B/C Ratio |          |           |           |           |
| Modified B/C Ratio     |          |           |           |           |

$$\text{Conv B/C} = \text{Delta Benefits} / (\text{AC of IC} - \text{Delta O\&M})$$

$$\text{Mod B/C} = (\text{Delta Benefits} + \text{Delta O\&M}) / \text{AE of IC}$$

| $i=9\%$ , $n=20$ yrs   | Current                      | Project A | Project B | Project C  |
|------------------------|------------------------------|-----------|-----------|------------|
| Initial Cost (\$)      | \$0                          | \$100,000 | \$175,000 | \$225,000  |
| Annual O&M Cost        | \$15,000                     | \$8,000   | \$10,000  | \$25,000   |
| Annual Benefits        | \$20,000                     | \$30,000  | \$35,000  | \$50,000   |
| A/E of IC              |                              | \$10,955  | \$19,171  | \$24,648   |
| Delta O&M              | As Bene Fit                  | \$7,000   | \$5,000   | (\$10,000) |
| Delta Benefits         |                              | \$10,000  | \$15,000  | \$30,000   |
| Conventional B/C Ratio | Reduced O&M<br>Reduces Cost  | 2.53      | 1.06      | 0.87       |
| Modified B/C Ratio     | Reduced O&M<br>Adds Benefits | 1.55      | 1.04      | 0.81       |

## Rate of Return

- In essence any cash stream may be represented by a polynomial:
- $PV = A_0 + A_1*(1+i) + A_2*(1+i)^2, \dots A_n()^n$  where A is any amount of \$\$'s
- The Internal Rate of Return (IRR) is that interest rate that causes the value of the equation to go to zero.
- Excel has a function that will find it, or "Trial and Error" as suggested by Halpin.

### Trial and Error IRR Calculation

| EOY | Amount |        |        |        |        |
|-----|--------|--------|--------|--------|--------|
| 0   | -8,000 | -8,000 | -8,000 | -8,000 | -8,000 |
| 1   | 2,000  | 1,818  | 1,667  | 1,600  | 1,633  |
| 2   | 3,000  | 2,479  | 2,083  | 1,920  | 1,999  |
| 3   | 4,000  | 3,005  | 2,315  | 2,048  | 2,176  |
| 4   | 5,000  | 3,415  | 2,411  | 2,048  | 2,220  |
| %   | 0%     | 10%    | 20%    | 25%    | 22.50% |
| NPW | 6,000  | 2,718  | 476    | -384   | 28     |

### Some Hints.

- In math terms the "curve" decreases monotonically to the right to cross the X-axis. Therefore,
- NPV at 0% must be a positive number. So check that first.
- If NPV at 0% is a large number, IRR must be large so pick you first % at 20% or more to bound the answer.

### RAT #02.4.2

- Pull out a sheet of paper and get your calculators ready.
- Take 5-minutes to compute the IRR of the cash flow table to the right.

| EOY | Amt        |
|-----|------------|
| 0   | \$ (6,000) |
| 1   | \$ 2,000   |
| 2   | \$ 2,000   |
| 3   | \$ 4,000   |

### RAT #3.3.2, Continued

- Check with your Pair and see if you got the same answer? If not why not? Take 2-minutes.
- Now do the same with within Teams.
- Team ? What answer did you get? Etc.

### Some More IRR Issues

- As you sum amounts from left to right, the cashflow equation changes sign at least once. Ill behaved cash flow may change sign more that once, indicating multiple roots.
- Ill behaved cashflows may approach the X-axis asymptotically implying an improbably large IRR.

### External Rate of Return

- Works for all types of cash flows – messy or otherwise.
- The Steps:
  1. Discount all expenses to the Present at the "prime" (what you have to pay) interest rate.
  2. Project all income to the Future at the "T-Bill" (what you can get) rate.
  3. Consolidate numbers and Solve resulting  $P=F/(1+i)^n$  for  $i$

## Example ERR

| Year  | Cash Flow | PV@8%  | FV@5%  |
|-------|-----------|--------|--------|
| 0     | 10,000    | 10,000 |        |
| 1     | 15,000    | 13,889 |        |
| 2     | 0         |        | 0      |
| 3     | 1,000     |        | 1,407  |
| 4     | 2,000     |        | 2,680  |
| 5     | 4,000     |        | 5,105  |
| 6     | 6,000     |        | 7,293  |
| 7     | 7,000     |        | 8,103  |
| 8     | 6,000     |        | 6,615  |
| 9     | 5,000     |        | 5,250  |
| 10    | 4,000     |        | 4,000  |
| 5.41% | 10,000    | 23,889 | 40,454 |

### Assume:

- 8% borrowing
- 5% earning
- Ten Year Project
- Cashflow as shown

## RAT #02.4.3

- Pull out a sheet of paper, get your calculators ready ... ..
- First As Individuals take 2 minutes to:
  - List the steps necessary to perform a ERR analysis.
- Then as pairs take 2 minutes to:
  - Combine and correct lists.

## RAT 02.4.3, Continued

- Now Individually work the problem.

| Year | Cash Flow | PV@8% | FV@5% |
|------|-----------|-------|-------|
| 0    | 10,000    |       |       |
| 1    | 15,000    |       |       |
| 2    | 0         |       |       |
| 3    | 1,000     |       |       |
| 4    | 2,000     |       |       |
| 5    | 4,000     |       |       |
| 6    | 6,000     |       |       |
| 7    | 7,000     |       |       |
| 8    | 6,000     |       |       |
| 9    | 5,000     |       |       |
| 10   | 4,000     |       |       |
|      | 10,000    |       |       |

### Assume:

- 10% borrowing
- 5% earning
- Ten Year Project
- Cashflow as shown

## When to Use Each Technique?

- It depends on what you are evaluating and who you are trying to convince.
- NPV adds to the "balance sheet" and the total worth of the organization or measures the value of an investment for "pricing" issues.
- B/C is required for most all Gov. projects.
- IRR% is how "investors" look at things. ERR% is more realistic but ... ..
- AE is how operators look at things and operating cashflow issues.

## Class Assessment

- In one sentence, which topic do you think needed to be covered in more detail?
